CHEMOKINE RECEPTORS 88-2B [CKR-3] AND 88C AND THEIR ANTIBODIES

This application is a continuation-in-part of U.S. Patent Application Serial No. 08/661,393 filed June 7, 1996 which was in turn a continuation-in-part of U.S. Patent Application No. 08/575,967 filed December 20, 1995.

FIELD OF THE INVENTION

The present invention relates generally to signal transduction pathways. More particularly, the present invention relates to chemokine receptors, nucleic acids encoding chemokine receptors, chemokine receptor ligands, modulators of chemokine receptor activity, antibodies recognizing chemokines and chemokine receptors, methods for identifying chemokine receptor ligands and modulators, methods for producing chemokine receptors, and methods for producing antibodies recognizing chemokine receptors.

BACKGROUND OF THE INVENTION

Recent advances in molecular biology have led to an appreciation of the central role of signal transduction pathways in biological processes. These pathways comprise a central means by which individual cells in a multicellular organism communicate, thereby coordinating biological processes. See *Springer, Cell* 76:301-314 (1994), Table I for a model. One branch of signal transduction pathways, defined by the intracellular participation of guanine nucleotide binding proteins (G-proteins), affects a broad range of biological processes.

Lewin, GENES V 319-348 (1994) generally discusses G-protein signal transduction pathways which involve, at a minimum, the following components: an extracellular signal (e.g., neurotransmitters, peptide hormones, organic molecules, light, or odorants), a signal-recognizing receptor (G-protein-coupled receptor, reviewed in *Probst et al., DNA and Cell Biology* 11:1-20 [1992] and also known as GPR or GPCR), and an intracellular, heterotrimeric GTP-binding protein, or G protein. In particular, these

pathways have attracted interest because of their role in regulating white blood cell or leukocyte trafficking.

Leukocytes comprise a group of mobile blood cell types including granulocytes (*i.e.*, neutrophils, basophils, and eosinophils), lymphocytes, and monocytes. When mobilized and activated, these cells are primarily involved in the body's defense against foreign matter. This task is complicated by the diversity of normal and pathological processes in which leukocytes participate. For example, leukocytes function in the normal inflammatory response to infection. Leukocytes are also involved in a variety of pathological inflammations. For a summary, see Schall *et al.*, *Curr. Opin. Immunol.* 6:865-873 (1994). Moreover, each of these processes can involve unique contributions, in degree, kind, and duration, from each of the leukocyte cell types.

In studying these immune reactions, researchers initially concentrated on the signals acting upon leukocytes, reasoning that a signal would be required to elicit any form of response. Murphy, *Ann. Rev. Immunol.* 12:593-633 (1994) has reviewed members of an important group of leukocyte signals, the peptide signals. One type of peptide signal comprises the chemokines (*chemoattractant cytokines*), termed intercrines in Oppenheim *et al.*, *Ann. Rev. Immunol.* 9:617-648 (1991). In addition to Oppenheim *et al.*, Baggiolini *et al.*, *Advances in Immunol.* 55:97-179 (1994), documents the growing number of chemokines that have been identified and subjected to genetic and biochemical analyses.

Comparisons of the amino acid sequences of the known chemokines have led to a classification scheme which divides chemokines into two groups: the α group characterized by a single amino acid separating the first two cysteines (CXC; N-terminus as referent), and the β group, where these cysteines are adjacent (CC). See Baggiolini *et al.*, *supra*. Correlations have been found between the chemokines and the particular leukocyte cell types responding to those signals. Schall *et al.*, *supra*, has reported that the CXC chemokines generally affect neutrophils; the CC chemokines tend to affect monocytes.

lymphocytes, basophils and eosinophils. For example, *Baggiolini et al., supra*, recited that RANTES, a CC chemokine, functions as a chemoattractant for monocytes, lymphocytes (*i.e.*, memory T cells), basophils, and eosinophils, but not for neutrophils, while inducing the release of histamine from basophils.

Chemokines were recently shown by Cocchi, *et al.*, *Science*, 270: 1811-1815 (1995) to be suppressors of HIV proliferation. Cocchi, *et al.* demonstrated that RANTES, MIP-1 α , and MIP-1 β suppressed HIV-1, HIV-2 and SIV infection of a CD4⁺ cell line designated PM1 and of primary human peripheral blood mononuclear cells.

Recently, however, attention has turned to the cellular receptors that bind the chemokines, because the extracellular chemokines seem to contact cells indiscriminately, and therefore lack the specificity needed to regulate the individual leukocyte cell types.

Murphy, supra, reported that the GPCR superfamily of receptors includes the chemokine receptor family. The typical chemokine receptor structure includes an extracellular chemokine-binding domain located near the N-terminus, followed by seven spaced regions of predominantly hydrophobic amino acids capable of forming membrane-spanning α -helices. Between each of the α -helical domains are hydrophilic domains localized alternately, in the intra- or extra-cellular spaces. These features impart a serpentine conformation to the membrane-embedded chemokine receptor. The third intracellular loop typically interacts with G-proteins. In addition, *Murphy, supra*, noted that the intracellular carboxyl terminus is also capable of interacting with G-proteins.

The first chemokine receptors to be analyzed by molecular cloning techniques were the two neutrophil receptors for human IL8, a CXC chemokine. *Holmes et al., Science* 253:178-1280 (1991) and *Murphy et al., Science* 253:1280-1283 (1991), reported the cloning of these two receptors for IL8. *Lee et al., J. Biol. Chem.* 267:16283-16287 (1992), analyzed the cDNAs encoding these receptors and found 77% amino acid identity between the encoded receptors, with each receptor exhibiting features of the G protein

coupled receptor family. One of these receptors is specific for IL-8, while the other binds and signals in response to IL-8, gro/MSGSA, and NAP-2. Genetic manipulation of the genes encoding IL-8 receptors has contributed to our understanding of the biological roles occupied by these receptors. For example, *Cacalano et al.*, *Science* 265:682-684 (1994) reported that deletion of the IL-8 receptor homolog in the mouse resulted in a pleiotropic phenotype involving lymphadenopathy and splenomegaly. In addition, a study of missense mutations described in *Leong et al.*, *J. Biol. Chem.* 269:19343-19348 (1994) revealed amino acids in the IL-8 receptor that were critical for IL-8 binding. Domain swapping experiments discussed in *Murphy, supra*, implicated the amino terminal extracellular domain as a determinant of binding specificity.

Several receptors for CC chemokines have also been identified and cloned. CCR1 binds both MIP-1 α and RANTES and causes intracellular calcium ion flux in response to both ligands. *Charo et al.*, *Proc Natl. Acad. Sci. (USA)* 91:2752-2756 (1994) reported that another CC chemokine receptor, MCP-R1 (CCR2), is encoded by a single gene that produces two splice variants which differ in their carboxyl terminal domains. This receptor binds and responds to MCP-3 in addition to MCP-1.

A promiscuous receptor that binds both CXC and CC chemokines has also been identified. This receptor was originally identified on red blood cells and *Horuk et al.*, *Science* 261:1182-1184 (1993) reports that it binds IL-8, NAP-2, GRO α , RANTES, and MCP-1. The erythrocyte chemokine receptor shares about 25% identity with other chemokine receptors and may help to regulate circulating levels of chemokines or aid in the presentation of chemokines to their targets. In addition to binding chemokines, the erythrocyte chemokine receptor has also been shown to be the receptor for *Plasmodium vivax*, a major cause of malaria (id.). Another G-protein coupled receptor which is closely related to chemokine receptors, the platelet activating factor receptor, has also been shown to be the receptor for a human pathogen, the bacterium *Streptococcus pneumoniae* (*Cundell et al.*, *Nature* 377:435-438 (1995)).

In addition to the mammalian chemokine receptors, two viral chemokine receptor homologs have been identified. Ahuja *et al.*, *J. Biol. Chem.* 268:20691-20694 (1993) describes a gene product from *Herpesvirus saimiri* that shares about 30% identity with the IL-8 receptors and binds CXC chemokines. Neote *et al.*, *Cell*, 72:415-425 (1993) reports that human cytomegalovirus contains a gene encoding a receptor sharing about 30% identity with the CC chemokine receptors which binds MIP-1 α , MIP-1 β , MCP-1, and RANTES. These viral receptors may affect the normal role of chemokines and provide a selective pathological advantage for the virus.

Because of the broad diversity of chemokines and their activities, there are numerous receptors for the chemokines. The receptors which have been characterized represent only a fraction of the total complement of chemokine receptors. There thus remains a need in the art for the identification of additional chemokine receptors. The availability of these novel receptors will provide tools for the development of therapeutic modulators of chemokine or chemokine receptor function. It is contemplated by the present invention that such modulators are useful as therapeutics for the treatment of atherosclerosis, rheumatoid arthritis, tumor growth suppression, asthma, viral infections, and other inflammatory conditions. Alternatively, fragments or variants of the chemokine receptors, or antibodies recognizing those receptors, are contemplated as therapeutics.

SUMMARY OF THE INVENTION

The present invention provides purified and isolated nucleic acids encoding chemokine receptors involved in leukocyte trafficking. Polynucleotides of the invention (both sense and anti-sense strands thereof) include genomic DNAs, cDNAs, and RNAs, as well as completely or partially synthetic nucleic acids. Preferred polynucleotides of the invention include the DNA encoding the chemokine receptor 88-2B that is set out in SEQ ID NO:3, the DNA encoding the chemokine receptor 88C that is set out in SEQ ID NO:1, and DNAs which hybridize to those DNAs under standard stringent hybridization conditions, or which would hybridize but for the redundancy of

the genetic code. Exemplary stringent hybridization conditions are as follows: hybridization at 42°C in 50% formamide, 5X SSC, 20 mM sodium phosphate, pH 6.8 and washing in 0.2X SSC at 55°C. It is understood by those of skill in the art that variation in these conditions occurs based on the length and GC nucleotide content of the sequences to be hybridized. Formulas standard in the art are appropriate for determining exact hybridization conditions. See *Sambrook et al.*, §§ 9.47-9.51 in *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York (1989). Also contemplated by the invention are polynucleotides encoding domains of 88-2B or 88C, for example, polynucleotides encoding one or more extracellular domains of either protein or other biologically active fragments thereof. 88-2B extracellular domains correspond to SEQ ID NO:3 and SEQ ID NO:4 at amino acid residues 1-36, 93-107, 171-196, and 263-284. The extracellular domains of 88-2B are encoded by polynucleotide sequences corresponding to SEQ ID NO:3 at nucleotides 362-469, 638-682, 872-949, and 1148-1213. Extracellular domains of 88C correspond to SEQ ID NO:1 and SEQ ID NO:2 at amino acid residues 1-32, 89-112, 166-191, and 259-280. The 88C extracellular domains are encoded by polynucleotide sequences that correspond to SEQ ID NO:1 at nucleotides 55-150, 319-390, 550-627, and 829-894. The invention also comprehends polynucleotides encoding intracellular domains of these chemokine receptors. The intracellular domains of 88-2B include amino acids 60-71, 131-151, 219-240, and 306-355 of SEQ ID NO:3 and SEQ ID NO:4. Those domains are encoded by polynucleotide sequences corresponding to SEQ ID NO:3 at nucleotides 539-574, 752-814, 1016-1081, and 1277-1426, respectively. The 88C intracellular domains include amino acid residues 56-67, 125-145, 213-235, and 301-352 of SEQ ID NO:1 and SEQ ID NO:2. The intracellular domains of 88C are encoded by polynucleotide sequences corresponding to SEQ ID NO:1 at nucleotides 220-255, 427-489, 691-759, and 955-1110. Peptides corresponding to one or more of the extracellular or intracellular domains, or antibodies raised against those peptides, are contemplated as modulators of receptor activities, especially ligand and G protein binding activities of the receptors.

The nucleotide sequences of the invention may also be used to design oligonucleotides for use as labeled probes to isolate genomic DNAs encoding 88-2B or 88C under stringent hybridization conditions (*i.e.*, by Southern analyses and Polymerase Chain Reaction methodologies). Moreover, these oligonucleotide probes can be used to detect particular alleles of the genes encoding 88-2B or 88C, facilitating both diagnosis and gene therapy treatments of disease states associated with particular alleles. In addition, these oligonucleotides can be used to alter chemokine receptor genetics to facilitate identification of chemokine receptor modulators. Also, the nucleotide sequences can be used to design antisense genetic elements of use in exploring or altering the genetics and expression of 88-2B or 88C. The invention also comprehends biological replicas (*i.e.*, copies of isolated DNAs made *in vivo* or *in vitro*) and RNA transcripts of DNAs of the invention. Autonomously replicating recombinant constructions such as plasmid, viral, and chromosomal (*e.g.*, YAC) nucleic acid vectors effectively incorporating 88-2B or 88C polynucleotides, and, particularly, vectors wherein DNA effectively encoding 88-2B or 88C is operatively linked to one or more endogenous or heterologous expression control sequences are also provided.

The 88-2B and 88C receptors may be produced naturally, recombinantly or synthetically. Host cells (prokaryotic or eukaryotic) transformed or transfected with polynucleotides of the invention by standard methods may be used to express the 88-2B and 88C chemokine receptors. Beyond the intact 88-2B or 88C gene products, biologically active fragments of 88-2B or 88C, analogs of 88-2B or 88C, and synthetic peptides derived from the amino acid sequences of 88-2B, set out in SEQ ID NO:4, or 88C, set out in SEQ ID NO:2, are contemplated by the invention. Moreover, the 88-2B or 88C gene product, or a biologically active fragment of either gene product, when produced in a eukaryotic cell, may be post-translationally modified (*e.g.*, via disulfide bond formation, glycosylation, phosphorylation, myristoylation, palmitoylation, acetylation, etc.) The invention further contemplates the 88-2B and 88C gene products, or biologically active

fragments thereof, in monomeric, homomultimeric, or heteromultimeric conformations.

In particular, one aspect of the invention involves antibody products capable of specifically binding to the 88-2B or 88C chemokine receptors. The antibody products are generated by methods standard in the art using recombinant 88-2B or 88C receptors, synthetic peptides or peptide fragments of 88-2B or 88C receptors, host cells expressing 88-2B or 88C on their surfaces, or 88-2B or 88C receptors purified from natural sources as immunogens. The antibody products may include monoclonal antibodies or polyclonal antibodies of any source or sub-type. Moreover, monomeric, homomultimeric, and heteromultimeric antibodies, and fragments thereof, are contemplated by the invention. Further, the invention comprehends CDR-grafted antibodies, "humanized" antibodies, and other modified antibody products retaining the ability to specifically bind a chemokine receptor.

The invention also contemplates the use of antibody products for detection of the 88-2B or 88C gene products, their analogs, or biologically active fragments thereof. For example, antibody products may be used in diagnostic procedures designed to reveal correlations between the expression of 88-2B, or 88C, and various normal or pathological states. In addition, antibody products can be used to diagnose tissue-specific variations in expression of 88-2B or 88C, their analogs, or biologically active fragments thereof. Antibody products specific for the 88-2B and 88C chemokine receptors may also act as modulators of receptor activities. In another aspect, antibodies to 88-2B or 88C receptors are useful for therapeutic purposes.

Assays for ligands capable of interacting with the chemokine receptors of the invention are also provided. These assays may involve direct detection of chemokine receptor activity, for example, by monitoring the binding of a labeled ligand to the receptor. In addition, these assays may be used to indirectly assess ligand interaction with the chemokine receptor. As used herein the term "ligand" comprises molecules which are agonists and antagonists of 88-2B or 88C, and other molecules which bind to the receptors.

Direct detection of ligand binding to a chemokine receptor may be achieved using the following assay. Test compounds (*i.e.*, putative ligands) are detectably labeled (*e.g.*, radioiodinated). The detectably labeled test compounds are then contacted with membrane preparations containing a chemokine receptor of the invention. Preferably, the membranes are prepared from host cells expressing chemokine receptors of the invention from recombinant vectors. Following an incubation period to facilitate contact between the membrane-embedded chemokine receptors and the detectably labeled test compounds, the membrane material is collected on filters using vacuum filtration. The detectable label associated with the filters is then quantitated. For example, radiolabels are quantitated using liquid scintillation spectrophotometry. Using this technique, ligands binding to chemokine receptors are identified. To confirm the identification of a ligand, a detectably labeled test compound is exposed to a membrane preparation displaying a chemokine receptor in the presence of increasing quantities of the test compound in an unlabeled state. A progressive reduction in the level of filter-associated label as one adds increasing quantities of unlabeled test compound confirms the identification of that ligand.

Agonists are ligands which bind to the receptor and elicit intracellular signal transduction and antagonists are ligands which bind to the receptor but do not elicit intracellular signal transduction. The determination of whether a particular ligand is an agonist or an antagonist can be determined, for example, by assaying G protein-coupled signal transduction pathways. Activation of these pathways can be determined by measuring intracellular Ca^{++} flux, phospholipase C activity or adenylyl cyclase activity, in addition to other assays (see examples 5 and 6).

As discussed in detail in the Examples herein, chemokines that bind to the 88C receptor include RANTES, MIP-1 α , and MIP-1 β , and chemokines that bind to the 88-2B receptor include RANTES.

In another aspect, modulators of the interaction between the 88C and 88-2B receptors and their ligands are specifically contemplated by the invention. Modulators of chemokine receptor function may be identified using

assays similar to those used for identifying ligands. The membrane preparation displaying a chemokine receptor is exposed to a constant and known quantity of a detectably labeled functional ligand. In addition, the membrane-bound chemokine receptor is also exposed to an increasing quantity of a test compound suspected of modulating the activity of that chemokine receptor. If the levels of filter-associated label correlate with the quantity of test compound, that compound is a modulator of the activity of the chemokine receptor. If the level of filter-associated label increases with increasing quantities of the test compound, an activator has been identified. In contrast, if the level of filter-associated label varies inversely with the quantity of test compound, an inhibitor of chemokine receptor activity has been identified. Testing for modulators of receptor binding in this way allows for the rapid screening of many putative modulators, as pools containing many potential modulators can be tested simultaneously in the same reaction.

The indirect assays for receptor binding involve measurements of the concentration or level of activity of any of the components found in the relevant signal transduction pathway. Chemokine receptor activation often is associated with an intracellular Ca^{++} flux. Cells expressing chemokine receptors may be loaded with a calcium-sensitive dye. Upon activation of the expressed receptor, a Ca^{++} flux would be rendered spectrophotometrically detectable by the dye. Alternatively, the Ca^{++} flux could be detected microscopically. Parallel assays, using either technique, may be performed in the presence and absence of putative ligands. For example, using the microscopic assay for Ca^{++} flux, RANTES, a CC chemokine, was identified as a ligand of the 88-2B chemokine receptor. Those skilled in the art will recognize that these assays are also useful for identifying and monitoring the purification of modulators of receptor activity. Receptor activators and inhibitors will activate or inhibit, respectively, the interaction of the receptors with their ligands in these assays.

Alternatively, the association of chemokine receptors with G proteins affords the opportunity of assessing receptor activity by monitoring

G protein activities. A characteristic activity of G proteins. GTP hydrolysis. may be monitored using, for example, ^{32}P -labeled GTP.

G proteins also affect a variety of other molecules through their participation in signal transduction pathways. For example, G protein effector molecules include adenylyl cyclase, phospholipase C, ion channels, and phosphodiesterases. Assays focused on any of these effectors may be used to monitor chemokine receptor activity induced by ligand binding in a host cell that is both expressing the chemokine receptor of interest and contacted with an appropriate ligand. For example, one method by which the activity of chemokine receptors may be detected involves measuring phospholipase C activity. In this assay, the production of radiolabeled inositol phosphates by host cells expressing a chemokine receptor in the presence of an agonist is detected. The detection of phospholipase activity may require cotransfection with DNA encoding an exogenous G protein. When cotransfection is required, this assay can be performed by cotransfection of chimeric G protein DNA, for example, Gqi5 (Conklin, *et al.*, *Nature* 363:274-276 (1993), with 88-2B or 88C DNA and detecting phosphoinositol production when the cotransfected cell is exposed to an agonist of the 88-2B or 88C receptor. Those skilled in the art will recognize that assays focused on G-protein effector molecules are also useful for identifying and monitoring the purification of modulators of receptor activity. Receptor activators and inhibitors will activate or inhibit, respectively, the interaction of the receptors with their ligands in these assays.

Chemokines have been linked to many inflammatory diseases, such as psoriasis, arthritis, pulmonary fibrosis and atherosclerosis. See Baggiolini *et al.*, *supra*. Inhibitors of chemokine action may be useful in treating these conditions. In one example, Broaddus *et al.*, *J. of Immunol.* 152:2960-2967 (1994), describes an antibody to IL-8 which can inhibit neutrophil recruitment in endotoxin-induced pleurisy, a model of acute inflammation in rabbit lung. It is also contemplated that ligand or modulator binding to, or the activation of, the 88C receptor may be useful in treatment of HIV infection and HIV related disease states. Modulators of chemokine

binding to specific receptors contemplated by the invention may include antibodies directed toward a chemokine or a receptor, biological or chemical small molecules, or synthetic peptides corresponding to fragments of the chemokine or receptor.

5 Administration of compositions containing 88-2B or 88C modulators to mammalian subjects, for the purpose of monitoring or remediating normal or pathological immune reactions And viral infections including infection by retroviruses such as HIV-1, HIV-2 and SIV is contemplated by the invention. In particular, the invention comprehends the
10 mitigation of inflammatory responses, abnormal hematopoietic processes, and viral infections by delivery of a pharmaceutically acceptable quantity of 88-2B or 88C chemokine receptor modulators. The invention further comprehends delivery of these active substances in pharmaceutically acceptable compositions comprising carriers, diluents, or medicaments. The invention
15 also contemplates a variety of administration routes. For example, the active substances may be administered by the following routes: intravenous, subcutaneous, intraperitoneal, intramuscular, oral, anal (*i.e.*, via suppository formulations), or pulmonary (*i.e.*, via inhalers, atomizers, nebulizers, etc.)

In another aspect, the DNA sequence information provided by
20 the present invention makes possible the development, by homologous recombination or "knockout" strategies [see, e.g. Kamekuchi, *Science*, 244:1288-1292 (1989)], of rodents that fail to express a functional 88C or 88-2B chemokine receptor or that express a variant of the receptor. Alternatively, transgenic mice which express a cloned 88-2B or 88C receptor
25 can be prepared by well known laboratory techniques (Manipulating the Mouse Embryo: A Laboratory Manual, Brigid Hohan, Frank Costantini and Elizabeth Lacy, eds. (1986) Cold Spring Harbor Laboratory ISBN 0-87969-175-1). Such rodents are useful as models for studying the activities of 88C or 88-2B receptors *in vivo*.

30 Other aspects and advantages of the present invention will become apparent to one skilled in the art upon consideration of the following examples.

DETAILED DESCRIPTION OF THE INVENTION

The following examples illustrate the invention. Example 1 describes the isolation of genomic DNAs encoding the 88-2B and 88C chemokine receptors. Example 2 presents the isolation and sequencing of cDNAs encoding human 88-2B and 88C and macaque 88C. Example 3 provides a description of Northern analyses revealing the expression patterns of the 88-2B and 88C receptors in a variety of tissues. Example 4 details the recombinant expression of the 88-2B and 88C receptors. Example 5 describes Ca⁺⁺ flux assays, phosphoinositol hydrolysis assays, and binding assays for 88-2B and 88C receptor activity in response to a variety of potential ligands. Experiments describing the role of 88C and 882B as co-receptors for HIV is presented in Examples 6 and 7. The preparation and characterization of monoclonal and polyclonal antibodies immunoreactive with 88C is described in Example 8. Example 9 describes additional assays designed to identify 88-2B or 88C ligands or modulators.

Example 1

Partial genomic clones encoding the novel chemokine receptor genes of this invention were isolated by PCR based on conserved sequences found in previously identified genes and based on a clustering of these chemokine receptor genes within the human genome. The genomic DNA was amplified by standard PCR methods using degenerate oligonucleotide primers.

Templates for PCR amplifications were members of a commercially available source of recombinant human genomic DNA cloned into Yeast Artificial Chromosomes (*i.e.*, YACs). (Research Genetics, Inc., Huntsville, AL. YAC Library Pools, catalog no. 95011 B). A YAC vector can accommodate inserts of 500-1000 kilobase pairs. Initially, pools of YAC clone DNAs were screened by PCR using primers specific for the gene encoding CCCKR1. In particular, CCCKR(2)-5', the sense strand primer (corresponding to the sense strand of CCCKR1), is presented in SEQ ID NO:15. Primer CCCKR(2)-5' consisted of the sequence 5'-CGTAAGCTTAGAGAAGCCGGGATGGGAA-3', wherein the underlined

nucleotides are the translation start codon for CCCKR1. The anti-sense strand primer was CCCKR-3' (corresponding to the anti-sense strand of CCCKR1) and its sequence is presented in SEQ ID NO:16. The sequence of CCCKR-3', 5'-GCCTCTAGAGTCAGAGACCAGCAGA-3', contains the reverse complement of the CCCKR1 translation stop codon (underlined). Pools of YAC clone DNAs yielding detectable PCR products (*i.e.*, DNA bands upon gel electrophoresis) identified appropriate sub-pools of YAC clones, based on a proprietary identification scheme. (Research Genetics, Inc., Huntsville, AL). PCR reactions were initiated with an incubation at 94°C for four minutes. Sequence amplifications were achieved using 33 cycles of denaturation at 94°C for one minute, annealing at 55°C for one minute, and extension at 72°C for two minutes.

The sub-pools of YAC clone DNAs were then subjected to a second round of PCR reactions using the conditions, and primers, that were used in the first round of PCR. Results from sub-pool screenings identified individual clones capable of supporting PCR reactions with the CCCKR-specific primers. One clone, 881F10, contained 640 kb of human genomic DNA from chromosome 3p21 including the genes for CCCKR1 and CCCKR2, as determined by PCR and hybridization. An overlapping YAC clone, 941A7, contained 700 kb of human genomic DNA and also contained the genes for CCCKR1 and CCCKR2. Consequently, further mapping studies were undertaken using these two YAC clones. Southern analyses revealed that CCCKR1 and CCCKR2 were located within approximately 100 kb of one another.

The close proximity of the CCCKR1 and CCCKR2 genes suggested that novel related genes might be linked to CCCKR1 and CCCKR2. Using DNA from yeast containing YAC clones 881F10 and 941A7 as templates, PCR reactions were performed to amplify any linked receptor genes. Degenerate oligodeoxynucleotides were designed as PCR primers. These oligonucleotides corresponded to regions encoding the second intracellular loop and the sixth transmembrane domain of CC chemokine receptors, as deduced from aligned sequence comparisons of CCCKR1,

CCCKR2, and V28. V28 was used because it is an orphan receptor that exhibits the characteristics of a chemokine receptor: V28 has also been mapped to human chromosome 3. *Raport et al.*, Gene 163:295-299 (1995). Of further note, the two splice variants of CCCKR2, CCCKR2A and CCCKR2B, are identical in the second intracellular loop and sixth transmembrane domain regions used in the analysis. The 5' primer, designated V28degf2, contains an internal *Bam*HI site (see below): its sequence is presented in SEQ ID NO:5. The sequence of primer V28degf2 corresponds to DNA encoding the second intracellular loop region of the canonical receptor structure. See *Probst et al., supra*. The 3' primer, designated V28degr2, contains an internal *Hind*III site (see below); its sequence is presented in SEQ ID NO:6. The sequence of primer V28degr2 corresponds to DNA encoding the sixth transmembrane domain of the canonical receptor structure.

Amplified PCR DNA was subsequently digested with *Bam*HI and *Hind*III to generate fragments of approximately 390 bp, consistent with the fragment size predicted from inspection of the canonical sequence. Following endonuclease digestion, these PCR fragments were cloned into pBluescript (Stratagene Inc., LaJolla, CA). A total of 54 cloned fragments were subjected to automated nucleotide sequence analyses. In addition to sequences from CCCKR1 and CCCKR2, sequences from the two novel chemokine receptor genes of the invention were identified. These two novel chemokine receptor genes were designated 88-2B and 88C.

Restriction endonuclease mapping and hybridization were utilized to map the relative positions of genes encoding the receptors 88C, 88-2B, CCCKR1, and CCCKR2. These four genes are closely linked, as the gene for 88C is approximately 18 KBP from the CCCKR2 gene on human chromosome 3p21.

Example 2

Full-length 88-2B and 88C cDNAs were isolated from a macrophage cDNA library by the following procedure. Initially, a cDNA library, described in *Tjoelker et al., Nature 374:549-553 (1995)*, was constructed in pRc/CMV (Invitrogen Corp., San Diego, CA) from human macrophage mRNA. The cDNA library was screened for the presence of 88-2B and 88C cDNA clones by PCR using unique primer pairs corresponding to 88-2B or 88C. The PCR protocol involved an initial denaturation at 94°C for four minutes. Polynucleotides were then amplified using 33 cycles of PCR under the following conditions: Denaturation at 94°C for one minute, annealing at 55°C for one minute, and extension at 72°C for two minutes. The first primer specific for 88-2B was primer 88-2B-f1, presented in SEQ ID NO:11. It corresponds to the sense strand of the gene encoding 88-2B was 844-863. The second PCR primer specific for the gene encoding 88-2B was primer 88-2B-r1, presented in SEQ ID NO:12; the 88-2B-r1 sequence corresponds to the anti-sense strand of SEQ ID NO:3 at nucleotides 1023-1042. Similarly, the sequence of the first primer specific for the gene encoding 88C, primer 88C-f1, is presented in SEQ ID NO:13 and corresponds to the sense strand of SEQ ID NO:1 at nucleotides 453-471. The second primer specific for the gene encoding 88C is primer 88C-r3, presented in SEQ ID NO:14; the sequence of 88C-r3 corresponds to the anti-sense strand of SEQ ID NO:1 at nucleotides 744-763.

The screening identified clone 777, a cDNA clone of 88-2B. Clone 777 contained a DNA insert of 1915 bp including the full length coding sequence of 88-2B as determined by the following criteria: the clone contained a long open reading frame beginning with an ATG codon, exhibited a Kozak sequence, and had an in-frame stop codon upstream. The DNA and deduced amino acid sequences of the insert of clone 777 are presented in SEQ ID NO:3 and SEQ ID NO:4, respectively. The 88-2B transcript was relatively rare in the macrophage cDNA library. During the library screen, only three 88-2B clones were identified from an estimated total of three million clones.

Screening for cDNA clones encoding the 88C chemokine receptor identified clones 101 and 134 which appeared to contain the entire 88C coding region, including a putative initiation codon. However, these clones lacked the additional 5' sequence needed to confirm the identity of the initiation codon. The 88C transcript was relatively abundant in the macrophage cDNA Library. During the library screen, it was estimated that 88C was present at one per 3000 transcripts (in a total of approximately three million clones in the library).

RACE PCR (Rapid Amplification of cDNA Ends) was performed to extend existing 88C clone sequences, thereby facilitating the accurate characterization of the 5' end of the 88C cDNA. Human spleen 5'-RACE-ready cDNA was purchased from Clontech Laboratories, Inc., Palo Alto, CA, and used according to the manufacturer's recommendations. The cDNA had been made "5'-RACE-ready" by ligating an anchor sequence to the 5' ends of the cDNA fragments. The anchor sequence is complementary to an anchor primer supplied by Clontech Laboratories, Inc., Palo Alto, CA. The anchor sequence-anchor primer duplex polynucleotide contains an *EcoRI* site. Human spleen cDNA was chosen as template DNA because Northern blots had revealed that 88C was expressed in this tissue. The PCR reactions were initiated by denaturing samples at 94°C for four minutes. Subsequently, sequences were amplified using 35 cycles involving denaturation at 94°C for one minute, annealing at 60°C for 45 seconds, and extension at 72°C for two minutes. The first round of PCR was performed on reaction mixtures containing 2 µl of the 5'-RACE-ready spleen cDNA, 1 µl of the anchor primer, and 1 µl of primer 88c-r4 (100 ng/µl) in a total reaction volume of 50 µl. The 88C-specific primer, primer 88c-r4 (5'-GATAAGCCTCACAG-CCCTGTG-3'), is presented in SEQ ID NO:7. The sequence of primer 88c-r4 corresponds to the anti-sense strand of SEQ ID NO:1 at nucleotides 745-765. A second round of PCR was performed on reaction mixtures including 1 µl of the first PCR reaction with 1 µl of anchor primer and 1 µl of primer 88C-rlb (100 ng/µl) containing the following sequence

- (5'-GCTAAGCTTGATGACTATCTTTAATGTC-3') and presented in SEQ ID NO:8. The sequence of primer 88C-rib contains an internal *Hind*III cloning site (underlined). The sequence 3' of the *Hind*III site corresponds to the anti-sense strand of SEQ ID NO:1 at nucleotides 636-654. The resulting PCR product was digested with *Eco*RI and *Hind*III and fractionated on a 1 % agarose gel. The approximately 700 bp fragment was isolated and cloned into pBluescript. Clones with the largest inserts were sequenced. Alternatively, the intact PCR product was ligated into vector pCR using a commercial TA cloning kit (Invitrogen Corp., San Diego, CA) for subsequent nucleotide sequence determinations.

- The 88-2B and 88C cDNAs were sequenced using the PRISM[™] Ready Reaction DyeDeoxy[™] Terminator Cycle Sequencing Kit (Perkin Elmer Corp., Foster City, CA) and an Applied Biosystems 373A DNA Sequencer. The insert of clone 777 provided the double-stranded template for sequencing reactions used to determine the 88-2B cDNA sequence. The sequence of the entire insert of clone 777 was determined and is presented as the 88-2B cDNA sequence and deduced amino acid sequence in SEQ ID NO:3. The sequence is 1915 bp in length, including 361 bp of 5' untranslated DNA (corresponding to SEQ ID NO:3 at nucleotides 1-361), a coding region of 1065 bp (corresponding to SEQ ID NO:3 at nucleotides 362-1426), and 489 bp of 3' untranslated DNA (corresponding to SEQ ID NO:3 at nucleotides 1427-1915). The 88-2B genomic DNA, described in Example 1 above, corresponds to SEQ ID NO:3 at nucleotides 746-1128. The 88C cDNA sequence, and deduced amino acid sequence, is presented in SEQ ID NO:1. The 88C cDNA sequence is a composite of sequences obtained from RACE-PCR cDNA, clone 134, and clone 101. The RACE-PCR cDNA was used as a sequencing template to determine nucleotides 1-654 in SEQ ID NO:1, including the unique identification of 9 bp of 5' untranslated cDNA sequence in SEQ ID NO:1 at nucleotides 1-9. The sequence obtained from the RACE PCR cDNA confirmed the position of the first methionine codon at nucleotides 55-57 in SEQ ID NO:1, and supported the conclusion that clone 134 and clone 101 contained full-length copies of the 88C coding region. Clone 134 contained

45 bp of 5' untranslated cDNA (corresponding to SEQ ID NO:1 at nucleotides 10-54), the 1056 bp 88C coding region (corresponding to SEQ ID NO:1 at nucleotides 55-1110), and 492 bp of 3' untranslated cDNA (corresponding to SEQ ID NO:1 at nucleotides 1111-1602). Clone 101 contained 25 bp of 5' untranslated cDNA (corresponding to SEQ ID NO:1 at nucleotides 30-54), the 1056 bp 88C coding region (corresponding to SEQ ID NO:1 at nucleotides 55-1110), and 2273 bp of 3' untranslated cDNA (corresponding to SEQ ID NO:1 at nucleotides 1111-3383). The 88C genomic DNA described in Example 1 above, corresponds to SEQ ID NO:1 at nucleotides 424-809.

The deduced amino acid sequences of 88-2B and 88C revealed hydrophobicity profiles characteristic of GPCRs, including seven hydrophobic domains corresponding to GPCR transmembrane domains. Sequence comparisons with other GPCRs also revealed a degree of identity. Significantly, the deduced amino acid sequences of both 88-2B and 88C had highest identity with the sequences of the chemokine receptors. Table 1 presents the results of these amino acid sequence comparisons.

Table 1

Chemokine Receptors	88-2B	88C
IL-8RA	30%	30%
IL-8RB	31%	30%
CCCKR1	62%	54%
CCCKR2A	46%	66%
CCCKR2B	50%	72%
88-2B	100%	50%
88-C	50%	100%

- 20 -

Table I shows that 88-2B is most similar to CCKR1 (62 % identical at the amino acid level) and 88C is most similar to CCKR2 (72 % identical at the amino acid level).

The deduced amino acid sequences of 88-2B and 88C also
 5 reveal the intracellular and extracellular domains characteristic of GPCRs.
 The 88-2B extracellular domains correspond to the amino acid sequence
 provided in SEQ ID NO:3, and SEQ ID NO:4, at amino acid residues 1-36,
 93-107, 171-196, and 263-284. The extracellular domains of 88-2B are
 encoded by polynucleotide sequences corresponding to SEQ ID NO:3 at
 10 nucleotides 362-469, 638-682, 872-949, and 1148-1213. Extracellular
 domains of 88C include amino acid residues 1-32, 89-112, 166-191, and 259-
 280 in SEQ ID NO:1 and SEQ ID NO:2. The 88C extracellular domains are
 encoded by polynucleotide sequences that correspond to SEQ ID NO:1 at
 nucleotides 55-150, 319-390, 550-627, and 829-894. The intracellular
 15 domains of 88-2B include amino acids 60-71, 131-151, 219-240, and 306-355
 of SEQ ID NO:3 and SEQ ID NO:4. Those domains are encoded by
 polynucleotide sequences corresponding to SEQ ID NO:3 at nucleotides 539-
 574, 752-814, 1016-1081, and 1277-1426, respectively. The 88C intracellular
 domains include amino acid residues 56-67, 125-145, 213-235, and 301-352
 20 of SEQ ID NO:1 and SEQ ID NO:2. The intracellular domains of 88C are
 encoded by polynucleotide sequences corresponding to SEQ ID NO:1 at
 nucleotides 220-255, 427-489, 691-759, and 955-1110.

In addition, a macaque 88C DNA was amplified by PCR from
 macaque genomic DNA using primers corresponding to 5' and 3' flanking
 25 regions of the human 88C cDNA. The 5' primer corresponded to the region
 immediately upstream of and including the initiating Met codon. The 3'
 primer was complementary to the region immediately downstream of the
 termination codon. The primers included restriction sites for cloning into
 expression vectors. The sequence of the 5' primer was
 30 GACAAGCTTCACAGGGTGAACAAAGATG (With the HindIII site underlined)
 (SEQ ID NO: 17) and the sequence of the 3' primer was
 GTCTCTAGACCACTTGAGTCCGTGTCA (with the XbaI site underlined) (SEQ ID

NO: 18). The conditions of the PCR amplification were 94°C for eight minutes, then 40 cycles of 94°C for one minute, 55°C for forty-five seconds, and 72°C one minute. The amplified products were cloned into the HindIII and XbaI sites of pcDNA3 and a clone was obtained and sequenced. The full length macaque cDNA and deduced amino acid sequences are presented in SEQ ID NOs: 19 and 20, respectively. The nucleotide sequence of macaque 88C is 98% identical to the human 88C sequence. The deduced amino acid sequences are 97% identical.

Example 3

The mRNA expression patterns of 88-2B and 88C were determined by Northern blot analyses.

Northern blots containing immobilized poly A⁺ RNA from a variety of human tissues were purchased from Clontech Laboratories, Inc., Palo Alto, CA. In particular, the following tissues were examined: heart, brain, placenta, lung, liver, skeletal muscle, kidney, pancreas, spleen, thymus, prostate, testis, ovary, small intestine, colon and peripheral blood leukocytes.

A probe specific for 88-2B nucleotide sequences was generated from cDNA clone 478. The cDNA insert in clone 478 contains sequence corresponding to SEQ ID NO: 3 at nucleotides 641-1915. To generate a probe, clone 478 was digested and the insert DNA fragment was isolated following gel electrophoresis. The isolated insert fragment was then radiolabeled with ³²P-labeled nucleotides, using techniques known in the art.

A probe specific for 88C nucleotide sequences was generated by isolating and radiolabeling the insert DNA fragment found in clone 493. The insert fragment from clone 493 contains sequence corresponding to SEQ ID NO: 1 at nucleotides 421-1359. Again, conventional techniques involving ³²P-labeled nucleotides were used to generate the probe.

Northern blots probed with 88-2B revealed an approximately 1.8 kb mRNA in peripheral blood leukocytes. The 88C Northern blots showed an approximately 4 kb mRNA in several human tissues, including a strong signal when probing spleen or thymus tissue and less intense signals when analyzing

mRNA from peripheral blood leukocytes and small intestine. A relatively weak signal for 88C was detected in lung tissue and in ovarian tissue.

- The expression of 88C in human T-cells and in hematopoietic cell lines was also determined by Northern blot analysis. Levels of 88C in
- 5 CD4⁺ and CD8⁺ T-cells were very high. The transcript was present at relatively high levels in myeloid cell lines THP1 and HL-60 and also found in the B cell line Jijoye. In addition, the cDNA was a relatively abundant transcript in a human macrophage cDNA library based on PCR amplification of library subfractions.

Example 4

- 10 The 88-2B and 88C cDNAs were expressed by recombinant methods in mammalian cells.

- For transient transfection experiments, 88C was subcloned into the mammalian cell expression vector pBJ1 (Ishi, K. *et. al.*, *J. Biol. Chem*
- 15 270:16435-16440 (1995). The construct included sequences encoding a prolactin signal sequence for efficient cell surface expression and a FLAG epitope at the amino terminus of 88C to facilitate detection of the expressed protein. The FLAG epitope consists of the sequence "DYKDDDD." COS-7
- 20 cells were transiently transfected with the 88C expression plasmid using Lipofectamine (Life Technology, Inc., Grand Island, NY) following the manufacturer's instructions. Briefly, cells were seeded in 24-well plates at a density of 4×10^4 cells per well and grown overnight. The cells were then washed with PBS, and 0.3 mg of DNA mixed with 1.5 μ l of lipofectamine in
- 25 0.25 ml of Opti-MEM was added to each well. After 5 hours at 37°C, the medium was replaced with medium containing 10% FCS. quantitative ELISA confirmed that 88C was expressed at the cell surface in transiently transfected COS-7 cells using the M1 antibody specific for the FLAG epitope (Eastman Co., New Haven, CT).

- The FLAG-tagged 88C receptor was also stably transfected into
- 30 HEK-293 cells, a human embryonic kidney cell line, using transfection reagent DOTAP (N-[1-[(2,3-Dioleoyloxy)propyl]-N,N,N-trimethyl-

ammoniummethylsulfate, Boehringer-Mannheim, Inc., Indianapolis, IN) according to the manufacturer's recommendations. Stable lines were selected in the presence of the drug G418. The transfected HEK-293 cells were evaluated for expression of 88C at the cell surface by ELISA, using the M1 antibody to the FLAG epitope. ELISA showed that 88C tagged with the FLAG epitope was expressed at the cell surface of stably transformed HEK-293 Cells.

The 88-2B and 88C cDNAs were used to make stable HEK-293 transfectants. The 88-2B receptor cDNA was cloned behind the cytomegalovirus promoter in pRc/CMV (Invitrogen Corp., San Diego, CA) using a PCR-based strategy. The template for the PCR reaction was the cDNA insert in clone 777. The PCR primers were 88-2B-3 (containing an internal *Xba*I site) and 88-2B-5 (containing an internal *Hind*III site). The nucleotide sequence of primer 88-2B-3 is presented in SEQ ID NO:9; the nucleotide sequence of primer 88-2B-5 is presented in SEQ ID NO:10. An 1104 bp region of cDNA was amplified. Following amplification, the DNA was digested with *Xba*I and *Hind*III and cloned into similarly digested pRc/CMV. The resulting plasmid was named 777XP2, which contains 18 bp of 5' untranslated sequence, the entire coding region of 88-2B, and 3 bp of 3' untranslated sequence. For the 88C sequence, the full-length cDNA insert in clone 134 was not further modified before transfecting HEK-293 cells.

To create stably transformed cell lines, the pRc/CMV recombinant clones were transfected using transfection reagent DOTAP-N-[1-[(2,3-Dioleoyloxy)propyl]-N,N,N-trimethylammoniummethylsulfate, Boehringer-Mannheim, Inc., Indianapolis, IN) according to the manufacturer's recommendations, into HEK-293 cells, a human embryonic kidney cell line. Stable lines were selected in the presence of the drug G418. Standard screening procedures (*i.e.*, Northern blot analyses) were performed to identify stable cell lines expressing the highest levels of 88-2B and 88C mRNA.

Example 5A. Ca⁺⁺ Flux Assays

To analyze polypeptide expression, a functional assay for chemokine receptor activity was employed. A common feature of signalling through the known chemokine receptors is that signal transduction is associated with the release of intracellular calcium cations. Therefore, intracellular Ca⁺⁺ concentration in the transfected HEK-293 cells was assayed to determine whether the 88-2B or 88C receptors responded to any of the known chemokines.

HEK-293 cells, stably transfected with 88-2B, 88C (without the FLAG epitope sequence), or a control coding region (encoding IL8R or CCKR2, see below) as described above, were grown in T75 flasks to approximately 90% confluence in MEM + 10% serum. Cells were then washed, harvested with versene (0.6 mM EDTA, 10 mM Na₂HPO₄, 0.14 M NaCl, 3 mM KCl, and 1 mM glucose), and incubated in MEM + 10% serum + 1 μ M Fura-2 AM (Molecular Probes, Inc., Eugene, OR) for 30 minutes at room temperature. Fura-2 AM is a Ca⁺⁺-sensitive dye. The cells were resuspended in Dulbecco's phosphate-buffered saline containing 0.9 mM CaCl₂ and 0.5 mM MgCl₂ (D-PBS) to a concentration of approximately 10⁷ cells/ml and changes in fluorescence were monitored using a fluorescence spectrophotometer (Hitachi Model F-4010). Approximately 10⁶ cells were suspended in 1.8 ml D-PBS in a cuvette maintained at 37°C. Excitation wavelengths alternated between 340 and 380 nm at 4 second intervals; the emission wavelength was 510 nm. Test compositions were added to the cuvette via an injection port; maximal Ca⁺⁺ flux was measured upon the addition of ionomycin.

Positive responses were observed in cells expressing IL-8RA when stimulated with IL-8 and also when CCKR2 was stimulated with MCP-1 or MCP-3. However, HEK-293 cells expressing either 88-2B or 88C failed to show a flux in intracellular Ca⁺⁺ concentration when exposed to any of the following chemokines: MCP-1, MCP-2, MCP-3, MIP-1 α , MIP-1 β , IL8,

NAP-2, gro/MGSA, IP-10, ENA-78, or PF-4. (Peprotech, Inc., Rocky Hill, NJ).

Using a more sensitive assay, a Ca^{++} flux response to RANTES was observed microscopically in Fura-2 AM-loaded cells expressing 88-2B. The assay involved cells and reagents prepared as described above. RANTES (Regulated on Activation, Normal T Expressed and Secreted) is a CC chemokine that has been identified as a chemoattractant and activator of eosinophils. See Neote *et al.*, *supra*. This chemokine also mediates a release of histamine by basophils and has been shown to function as a chemoattractant for memory T cells *in vitro*. Modulation of 88-2B receptor activities is therefore contemplated to be useful in modulating leukocyte activation.

FLAG tagged 88C receptor was expressed in HEK-293 cells and tested for chemokine interactions in the Ca^{++} flux assay. Cell surface expression of 88C was confirmed by ELISA and by FACScan analysis using the M1 antibody. The chemokines RANTES, MIP-1 α , and MIP-1 β all induced a Ca^{++} flux in 88C-transfected cells when added at a concentration of 100 nM.

Ca^{++} flux assays can also be designed to identify modulators of chemokine receptor binding. The preceding fluorimetric or microscopic assays are carried out in the presence of test compounds. If Ca^{++} flux is increased in the presence of a test compound, that compound is an activator of chemokine receptor binding. In contrast, a diminished Ca^{++} flux identifies the test compound as an inhibitor of chemokine receptor binding.

25 B. Phosphoinositol Hydrolysis

Another assay for ligands or modulators involves monitoring phospholipase C activity, as described in Hung *et al.*, *J. Biol. Chem.* 116:827-832 (1992). Initially, host cells expressing a chemokine receptor are loaded with 3H -inositol for 24 hours. Test compounds (*i.e.*, potential ligands) are then added to the cells and incubated at 37°C for 15 minutes. The cells are then exposed to 20 mM formic acid to solubilize and extract hydrolyzed

metabolites of phosphoinositol metabolism (*i.e.*, the products of phospholipase C-mediated hydrolysis). The extract is subjected to anion exchange chromatography using an AG1X8 anion exchange column (formate form). Inositol phosphates are eluted with 2 M ammonium formate/0.1 M formic acid and the ^3H associated with the compounds is determined using liquid scintillation spectrophotometry. The phospholipase C assay can also be exploited to identify modulators of chemokine receptor activity. The aforementioned assay is performed as described, but with the addition of a potential modulator. Elevated levels of detectable label would indicate the modulator is an activator; depressed levels of the label would indicate the modulator is an inhibitor of chemokine receptor activity.

The phospholipase C assay was performed to identify chemokine ligands of the FLAG-tagged 88C receptor. Approximately 24 hours after transfection, COS-7 cells expressing 88C were labeled for 20-24 hours with *myo*-[2- ^3H]inositol (1 $\mu\text{Ci}/\text{ml}$) in inositol-free medium containing 10% dialyzed FCS. Labeled cells were washed with inositol-free DMEM containing 10 mM LiCl and incubated at 37°C for 1 hour with inositol-free DMEM containing 10 mM LiCl and one of the following chemokines: RANTES, MIP-1 β , MIP-1 α , MCP-1, IL-8, or the murine MCP-1 homolog JE. Inositol phosphate (IP) formation was assayed as described in the previous paragraph. After incubation with chemokines, the medium was aspirated and cells were lysed by addition of 0.75 ml of ice-cold 20 mM formic acid (30 min). Supernatant fractions were loaded onto AG1-X8 Dowex columns (Biorad, Hercules, CA), followed by immediate addition of 3 ml of 50 mM NH_4OH . The columns were then washed with 4 ml of 40 mM ammonium formate, followed by elution with 2 M ammonium formate. Total inositol phosphates were quantitated by counting beta-emissions.

Because it has been shown that some chemokine receptors, such as IL8RA AND IL8RB, require cotransfection with an exogenous G protein before signalling can be detected in COS-7 cells, the 88C receptor was co-expressed with the chimeric G protein Gqi5 (Conklin, *et al.*, *Nature* 363:274-276, (1993). Gqi5 is a G protein which has the carboxyl terminal five amino

acids of Gi (which bind to the receptor) spliced onto G α q. Co-transfection with Gq15 significantly potentiates signaling by CCCKR1 and CCKR2B. Co-transfection with Gq15 revealed that 88C signaled well in response to RANTES, MIP-1 β , and MIP-1 α , but not in response to MCP-1, IL-8 or the murine MCP-1 homologue JE. Dose-response curves revealed EC₅₀ values of 1nM for RANTES, 6nM for MIP-1 β , and 22nM for MIP-1 α .

88C is the first cloned human receptor with a signaling response to MIP-1 β . Compared with other CC chemokines, MIP-1 β clearly has a unique cellular activation pattern. It appears to activate T cells but not monocytes (Baggiolini et al., Supra) which is consistent with receptor stimulation studies. For example, while MIP-1 β binds to CCCKR1, it does not induce calcium flux (Neote et al., Supra). In contrast, MIP-1 α and RANTES bind to and causes signalling in CCCKR1 and CCCKR5 (RANTES also causes activation of CCCKR3). MIP-1 β thus appears to be much more selective than other chemokines of the CC chemokine family. Such selectivity is of therapeutic significance because a specific beneficial activity can be stimulated (such as suppression of HIV infection) without stimulating multiple leukocyte populations which results in general pro-inflammatory activities.

C. BINDING ASSAYS

Another assay for receptor interaction with chemokines was a modification of the binding assay described by Ernst et al. *J. Immunol.* 152:3541-3549 (1994). MIP-1 β as labeled using the Bolton and Hunter reagent (di-iodide, NEN, Wilmington, DE), according to the manufacturer's instructions. Unconjugated iodide was separated from labeled protein by elution using a PD-10 column (Pharmacia) equilibrated with PBS and BSA (1% w/v). The specific activity was typically 2200 Ci/mmol. Equilibrium binding was performed by adding ¹²⁵I-labeled ligand with or without a 100-fold excess of unlabeled ligand, to 5 X 10⁵ HEK-293 cells transfected with 88C tagged with the FLAG epitope in polypropylene tubes in a total volume of 300 μ l (50 mM HEPES pH 7.4, 1 mM CaCl₂, MgCl₂, 0.5% BSA) and incubating for 90 minutes at 27°C with shaking at 150 rpm. The cells were

collected, using a Skatron cell harvester (Skatron Instruments Inc., Sterling, VA), on glass fiber filters presoaked in 0.3% polyethyleneimine and 0.2% BSA. After washing, the filters were removed and bound ligand was quantitated by counting gamma emissions. Ligand binding by competition with unlabeled ligand was determined by incubation of 5×10^4 transfected cells (as above) with 1.5 nM of radiolabeled ligand and the indicated concentrations of unlabeled ligand. The samples were collected, washed and counted as above. The data was analyzed using the curve-fitting program Prism (GraphPad Inc., San Diego, CA) and the iterative non-linear regression program, LIGAND (PM220).

In equilibrium binding assays, 88C receptor bound radiolabeled MIP-1 β in a specific and saturable manner. Analysis of this binding data by the method of Scatchard revealed a dissociation constant (Kd) of 1.6 nM. Competition binding assays using labeled MIP-1 β revealed high-affinity binding of MIP-1 β (IC₅₀ = 7.4 nM), RANTES (IC₅₀ = 6.9 nM), and MIP-1 α (IC₅₀ = 7.4 nM), consistent with the signaling data obtained in transiently transfected COS-7 cells as discussed in section B above.

Example 6

The chemokines MIP-1 α , MIP-1 β and RANTES have been shown to inhibit replication of HIV-1 and HIV-2 in human peripheral blood mononuclear cells and PM1 cells (Cocchi, *et al.*, *supra*). In view of this finding and in view of the results described in Example 5, the present invention contemplates that activation of or ligand binding to the 88C receptor may provide a protective role in HIV infection.

Recently, it has been reported that the orphan G protein-coupled receptor, fusin, can act as a co-receptor for HIV entry. Fusin/CXCR4 in combination with CD4, the primary HIV receptor, apparently facilitates HIV infection of cultured T cells (Feng, *et al.*, *Science* 272:872-877 (1996)). Based upon the homology of fusin to chemokine receptors and the chemokine binding profile of 88C, and because 88C is constitutively expressed in T cells

and abundantly expressed in macrophages, 88C is likely to be involved in viral and HIV infection.

The function of 88C and 88-2B as co-receptors for HIV was determined by transfecting cells which express CD4 with 88C or 88-2B and challenging the co-transfected cells with HIV. Only cells expressing both CD4 and a functional co-receptor for HIV become infected. HIV infection can be determined by several methods. ELISAs which test for expression of HIV antigens are commercially available, for example Coulter HIV-1 p24 antigen assay (US Patent Nos. 4,886,742), Coulter Corp., 11800 SW 147th Ave., Miami, FL 33196. Alternatively, the test cells can be engineered to express a reporter gene such as *LACZ* attached to the HIV LTR promoter [Kimpton *et al.*, *J. Virol.* 66:2232-2239 (1992)]. In this method, cells that are infected with HIV are detected by a colorimetric assay.

88C was transiently transfected into a cat cell line, CCC [Clapham, *et al.*, 181:703-715 (1991)], which had been stably transformed to express human CD4 (CCC-CD4). These cells are normally resistant to infection by any strain of HIV-1 because they do not endogenously express 88C. In these experiments, CCC/CD4 cells were transiently transfected with 88C cloned into the expression vector pcDNA3.1 (Invitrogen Corp., San Diego, CA) using lipofectamine (Gibco BRL, Gaithersburg, MD). Two days after transfection, cells were challenged with HIV. After 4 days of incubation, cells were fixed and stained for p24 antigen as a measure of HIV infection. 88C expression by these cells rendered them susceptible to infection by several strains of HIV-1. These strains included four primary non-syncytium-inducing HIV-1 isolates (M23, E80, SL-2 and SF-162) which were shown to use only 88C as a co-receptor but not fusin. Several primary syncytium-inducing strains of HIV-1 (2006, M13, 2028 and 2076) used either 88C or fusin as a co-receptor. Also, two established clonal HIV-1 viruses (GUN-1 and 89.6) used either 88C or fusin as a co-receptor.

It has been reported that some strains of HIV-2 can infect certain CD4-negative cell lines, thus implying a direct interaction of HIV-2 with a receptor other than CD4 [Clapham, *et al.*, *J. Virol.* 66:3531-3537

(1992)] For some strains of HIV-2, this infection is facilitated by the presence of soluble CD4 (sCD4). Since 88-2B shares high sequence similarity with other chemokine receptors that act as HIV co-receptors (namely 88C and fusin). 88-2B was considered to be a likely HIV-2 co-receptor. The role of 88-2B as an HIV-2 co-receptor was demonstrated using HIV-2 strain ROD/B. Cat CCC cells which do not endogeneously express CD4 were transfected with 88-2B. In these experiments, cells were transfected with pcDNA3.1 containing 88-2B using lipofectamine and infected with HIV-2 48 hours later. Three days after infection, cells were immunostained for the presence of HIV-2 envelope glycoproteins. The presence of sCD4 during HIV-2_{ROD/B} challenge increased the infection of these cells by 10-fold. The entry of HIV-2 into the 88-2B transfected cells could be blocked by the presence of 400-800 ng/ml eotaxin, one of the ligands for 88-2B. The baseline infectivity levels of CCC/88-2B (with no soluble CD4) were equivalent to CCC cells which were not transfected with 88-2B.

The role of 88-2B and 88C as co-receptors for HIV was confirmed by preparing and challenging cell lines stably transformed to express 88C or 88-2B with various strains of HIV and SIV. These results are described in Example 7.

Alternatively, the co-receptor role of 88C and 88-2B can be demonstrated by an experimental method which does not require the use of live virus. In this method, cell lines co-expressing 88C or 88-2B, CD4 and a *LACZ* reporter gene are mixed with a cell line co-expressing the HIV envelope glycoprotein (ENV) and a transcription factor for the reporter gene construct (Nussbaum, *et al.*, 1994 *J. Virol.* 68:5411). Cells expressing a functional co-receptor for HIV will fuse with the ENV expressing cells and thereby allow expression of the reporter gene. In this method, detection of reporter gene product by colorimetric assay indicates that 88C or 88-2B function as a co-receptor for HIV.

The mechanism by which chemokines inhibit viral infection has not yet been elucidated. One possible mechanism involves activation of the receptor by binding of a chemokine. The binding of the chemokine leads to

signal transduction events in the cell that renders the cell resistant to viral infection and/or prevents replication of the virus in the cell. Similar to interferon induction, the cell may differentiate such that it is resistant to viral infection, or an antiviral state is established. Alternatively, a second mechanism involves direct interference with viral entry into cells by blocking access of viral envelope glycoproteins to the co-receptor by chemokine binding. In this mechanism, G-protein signalling is not required for chemokine suppression of HIV infection.

To distinguish between two mechanisms by which 88C or 88-2B may function as co-receptors for viral or HIV infection, chemokine binding to the receptor is uncoupled from signal transduction and the effect of the chemokine on suppression of viral infection is determined.

Ligand binding can be uncoupled from signal transduction by the addition of compounds which inhibit G-protein mediated signaling. These compounds include, for example, pertussis toxin and cholera toxin. In addition, downstream effector polypeptides can be inhibited by other compounds such as wortmannin. If G-protein signalling is involved in suppression of viral infection, the addition of such compounds would prevent suppression of viral infection by the chemokine. Alternatively, key residues or receptor domains of 88C or 88-2B receptor required for G-protein coupling can be altered or deleted such that G-protein coupling is altered or destroyed but chemokine binding is not affected.

Under these conditions, if chemokines are unable to suppress viral or HIV infection, then signaling through a G-protein is required for suppression of viral or HIV infection. If however, chemokines are able to suppress viral infection, then G-protein signaling is not required for chemokine suppression of viral infection and the protective effects of chemokines may be due to the chemokine blocking the availability of the receptor for the virus.

Another approach involves the use of antibodies directed against 88C or 88-2B. Antibodies which bind to 88C or 88-2B which can be shown not to elicit G-protein signaling may block access to the chemokine or viral

binding site of the receptor. If in the presence of antibodies to 88C or 88-2B, viral infection is suppressed, then the mechanism of the protective effects of chemokines is blocking viral access to its receptor. Feng, *et al.* Reported that antibodies to the amino terminus of the fusin receptor suppressed HIV infection (Feng, *et al.*, 1996).

Example 7

Cell lines were stably transformed with 88C or 88-2B to further delineate the role of 88C and 88-2B in HIV infection. Kimpton and Emerman, "Detection of Replication-Competent and Pseudotyped Human Immunodeficiency Virus with a Sensitive Cell Line on the Basis of Activation of an Integrated Beta-Galactosidase Gene," *J. Virol.*, 66(5):3026-3031 (1992) previously described an indicator cell line, herein identified as HeLa-MAGI cells. HeLa-MAGI cells are HeLa cells that have been stably transformed to express CD4 as well as integrated HIV-1 LTR which drives expression of a nuclear localized β -galactosidase gene. Integration of an HIV provirus in the cells leads to production of the viral transactivator, Tat, which then turns on expression of the β -galactosidase gene. The number of cells that stain positive with X-gal for β -galactosidase activity *in situ* is directly proportional to the number of infected cells.

These HeLa-MAGI cells can detect lab-adapted isolates of HIV-1 but only a minority of primary isolates [Kimpton and Emerman, *supra*], and cannot detect most SIV isolates [Chackerian *et al.*, "Characterization of a CD4-Expressing Macaque Cell Line that can Detect Virus After A Single Replication Cycle and can be infected by Diverse Simian Immunodeficiency Virus Isolates," *Virology*, 213(2):6499-6505 (1995)].

In addition, Harrington and Geballe, "Co-Factor Requirement for Human Immunodeficiency Virus Type 1 Entry into a CD4-Expressing Human Cell Line," *J. Virol.*, 67:5939-5947 (1993) described a cell line based on U373 cells that had been engineered to express CD4 and the same LTR- β -galactosidase construct. It was previously shown that this cell line, herein identified as U373-MAGI, could not be infected with any HIV (M or T-tropic)

strain of HIV, but could be rendered susceptible to infection by fusion with HeLa cells [Harrington and Geballe, *supra*].

In order to construct indicator cell lines that could detect either Macrophage or T cell tropic viruses, epitope-tagged 88C or 88-2B encoding DNA was transfected into HeLa-MAGI or U373-MAGI cells by infection with a retroviral vector to generate HeLa-MAGI-88C or U373-MAGI-88C cell lines, respectively. Expression of the co-receptors on the cell surface was demonstrated by immunostaining live cells using the anti-FLAG M1 antibody and by RT-PCR.

The 88C and 88-2B genes utilized to construct HeLa-MAGI-88C and U373-MAGI-88C included sequences encoding the prolactin signal peptide followed by a FLAG epitope as described in Example 4. This gene was inserted into the retroviral vector pBabe-Puro [Morgenstern and Land *Nucleic Acids Research*, 18(12):3587-3596 (1990)]. High titer retroviral vector stocks pseudotyped with the VSV-G protein were made by transient transfection as described in Bartz *et al.*, *J. Virol.* 70:2324-2331 (1996), and used to infect HeLa-MAGI and U373-MAGI cells. Cells resistant to 0.6 μ g/ml puromycin (HeLa) or 1 μ g/ml puromycin (U373) were pooled. Each pool contained at least 1000 independent transduction events. An early passage (passage 2) stock of the original HeLa-MAGI cells [Kimpton and Emerman, *supra*] was used to create HeLa-MAGI-88C cells.

Infections of the indicator cell lines with HIV were performed in 12-well plates with 10-fold serial dilutions of 300 μ l of virus in the presence of 30 μ g/ml DEAE-Dextran as described [Kimpton and Emerman, *supra*].

All HIV-1 strains and SIV_{mac239} were all obtained from the NIH AIDS Reference and Reagent Program. Molecular clones of primary HIV-2_{712A} [Gao *et al.*, "Genetic Diversity of Human Immunodeficiency Virus Type 2: Evidence for Distinct Sequence Subtypes with Differences in Virus Biology," *J. Virol.*, 68(11):7433-7447 (1992)] and SIVsmPbJ1.9 [Dewhurst *et al.*, "Sequence Analysis and Acute Pathogenicity of Molecularly Cloned SIV_{sim}-PBj14," *Nature*, 345:636-640 (1990)] were obtained from B. Hahn

- 34 -

(UAB). All other SIV_{mac} isolates were obtained from Julie Overbaugh (U. Washington, Seattle). Stocks from cloned proviruses were made by transient transfection of 293 cells. Other viral stocks were made by passage of virus in human peripheral blood mononuclear cells or in CEMx174 cells (for SIV stocks.) Viral stocks were normalized by ELISA or p24^{EL} (Coulter Immunology) or p27^{EL} (Coulter Immunology) for HIV-1 and HIV-2/SIV, respectively, using standards provided by the manufacturer.

U373-MAGI-88C cells and U373-MAGI cells (controls) and were infected with limiting dilutions of a T-tropic strain of HIV-1 (HIV_{LAI}), an M-tropic strain (HIV_{YU-2}), and an SIV isolate, SIV_{MAC239}. Infectivity was measured by counting the number of blue cells per well per volume of virus (Table 2).

Table 2

virus strain ^a	titer on cell line (IU/ml) ^b	
	U373-MAGI	U373-MAGI-88C
HIV-1 _{LAI}	< 100	< 100
HIV-1 _{YU-2}	< 100	2.2 x 10 ⁶
SIV _{MAC239}	1.2 x 10 ³	4 x 10 ³

^a Viruses derived by transfection of molecular clones into 293 cells.

^b Infectious units (IU) per ml is the number of blue cells per well multiplied by the dilution of virus supernatant and normalized to 1 ml final volume.

Two days after infection, cells were fixed and stained for β -galactosidase activity with X-gal. The U373-derived MAGI cells were stained for 120 minutes at 37°C and the HeLa-derived MAGI cells were stained for 50 minutes at 37°C. Background staining of non-infected cells never exceeded more than approximately three blue cells per well. Only dark blue cells were counted, and syncytium with multiple nuclei were counted as a single infected cell. The infectious titer is the number of blue cells per well multiplied by the dilution of virus and normalized to 1 ml. The titer of
